

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

ucts. One striking fact that has turned up in every attempt to measure the outcomes of teaching is the wide variation found in individual achievement. This wide variability in human achievement has caused school people, in very recent years, to become interested in means or agencies for grouping students for purposes of instruction. Dr. Fretwell's study¹ is an attempt to answer the question concerning the extent to which a pupil's academic success can be foretold on the basis of standardized tests.

The experiment was carried out in the Speyer Junior High School for boys. The following conclusions are drawn:

"1. Academic success in the first year of junior high school was more successfully predicted by a group of standardized tests than by all previous school marks or age or teachers' estimates.

"2. The tests in the order of their importance for the purposes of this study, when the administration and the scoring of the tests are considered, have been found to be: reading, visual vocabulary, opposites, spelling, completion, arithmetic, easy directions, mixed relations, and composition." [Page 50.]

Educational diagnosis of individual pupils.—Several attempts have been made, heretofore, to measure the attainments of children in the group and to diagnose the results for purposes of remedying the teaching. While the individual has received some consideration, the main emphasis has been placed on group attainments and group remedial work. Dr. Buckner's study² is an attempt to investigate the possibility of diagnosing an individual case by means of standardized tests and scales, and, on the basis of the diagnosis, "to prescribe specific mental work" for the individual.

Seventy-two boys in the experimental academic junior high school recently organized at the Speyer School of Teachers College furnished the subjects for the investigation. Eleven standardized educational and psychological tests and scales were administered to this group at three different times, February, 1916, February, 1917, and June, 1917.

A major fact which turns up in this as in other measurements of individual attainments is the "extreme variability in individual cases."

The author finds "a considerable amount of relation between the ability of these pupils to achieve in these tests and the consistency or lack of variability in their achievements."

A study of school failures.—One of the chief measures of a functioning school system is the nature and amount of progress made by the pupils throughout the system. Hence, any study which attempts to investigate why children fail touches a most vital problem in the administration of public education. One of the most exhaustive and thoroughgoing studies³ in this field has recently appeared.

² CHESTER A. BUCKNER, *Educational Diagnosis of Individual Pupils*. Teachers College Contributions to Education, No. 98. New York: Teachers College, Columbia University, 1919. Pp. ix+93.

³ FRANCIS P. O'BRIEN, *The High School Failures*. Teachers College Contributions to Education, No. 102. New York: Teachers College, Columbia University, 1919. Pp. vii+97.

This study assumes that the "causes of and remedies for failure are necessarily closely connected with factors found in the school and with the school experiences of failing pupils." The study is based on the high-school records of 6,141 pupils belonging to eight different high schools located in New York and New Jersey.

The investigation attempts to answer the following questions: (1) How extensive are the failures of the high school? (2) What basis is discoverable for prognosticating the occurrence of, or the number of, failures? (3) How much is the graduation or the persistence in school conditioned by the occurrence or the number of failures? (4) Are the school agencies employed in remedying failures adequate for the purpose? (5) Do the failures represent a lack of capability or of fitness for high-school work on the part of those pupils? (6) What treatment is suggested by the diagnosis of the facts of failure?

Limitations of space prevent a rehearsal of the findings brought to light through the investigation of these specific problems. Suffice it to say that the study should be read by every high-school teacher and administrator.

A new scale for measuring hand sewing.—The measurement movement set in motion a little over a decade ago by Dr. E. L. Thorndike seems to be penetrating every field of educational endeavor. The present monograph¹ is an account of how a scale has been constructed to measure the products of hand sewing. The author made an effort to do some seven tasks in this piece of research, among which were to make a scale by means of which merit in certain forms of hand sewing may be measured, to make an inventory and analysis of the faults found in children's sewing, to determine the relative importance of various faults and of various stitches as indicators of general merit in sewing, and to determine the reliability of judgments concerning various faults and concerning various stitches.

The sewing of over one thousand persons formed the material for the investigation. Three hundred forty-seven persons rendered judgments upon the work. The scale itself consists of a series of fifteen plates upon which are the photographs of the different grades of sewing. By placing the work one wishes to judge alongside the different plates, one can fairly readily match the work in hand, and as each plate has a numerical value, one can in a way measure the sewing of the child. The theory is much like that used in building, writing, and composition scales, but has a little different turn. It appeals to us as being a very practical attack upon the problem of measuring hand work in sewing.

Efficient distribution of periods of practice.—The tendency to learn through experimentation the truth about matters pertaining to education is further illustrated by a monograph² from Teachers College which has just reached our desk. The author has made a very elaborate series of experiments to show whether it is more effective in learning to practice in periods of equal length, or to practice the same amount of time but have the time broken into periods of decreasing length. Seemingly, all the factors that could possibly affect the results were kept constant
